INTERNET OUTAGE — 19 OCTOBER 2026

Summary

The evidence supports a shared Internet-path interruption lasting approximately 12.5 minutes, with recovery by about 09:54 EDT and no operator modem power cycle. Cloudflare, Google and Quad9 public-IP pings failed together while the local pfSense gateway remained reachable. Traffic levels do not support local WAN saturation as the explanation. The available telemetry cannot locate the fault precisely within the modem, coax access network or upstream ISP path.

Scope and operator observations

Dashboard window: 13:33:54.858–14:40:38.520 UTC, or 09:33:54.858–10:40:38.520 EDT (America/New_York, UTC−04:00). Raw evidence includes five extra minutes of lead-in for counter calculations. The operator reported approximately 09:42–09:54, no modem power cycle, and a separate pfSense Unbound issue prolonging some service failures. Internet recovery is defined by public-IP ping recovery, not the later HTTPS recovery. Unbound causation is operator-reported; no resolver logs were collected.

Timeline (EDT; add four hours for UTC)

09:41:04–09:41:19: First sharply degraded 15-second reply-count interval for all three public targets. Cloudflare and Google receive no replies; Quad9 receives one. Sending continues. Thus the telemetry places onset slightly before the operator's approximate 09:42 observation.
09:41:53: One-minute loss records show 100% Cloudflare/Google loss and 97.78% Quad9 loss. All three are at 100% from 09:42:53 through 09:52:53 inclusive.
09:43:29: One modem collection failure is observed, with a 5.009-second poll duration and the collection error counter increasing from zero to one. Collection is successful again at 09:44:29. These are scrape observation times; polling happens earlier, independently of scraping.
09:53:34–09:53:49: Replies resume at all three public targets (3, 4 and 3 replies in this interval). Direct public DNS probes first succeed again at 09:53:46 (Cloudflare) and 09:53:51 (Google).
09:53:49–09:54:04: All three public targets receive 15 replies for 15 requests. Use approximately 09:54 as Internet recovery. Approximate onset-to-first-replies duration is 12m15s–12m45s based on sample boundaries; these are not packet capture timestamps.
09:54:53: One-minute loss is 0% Google/Quad9 and 2.22% Cloudflare. All three are 0% from 09:55:53 through the end of the requested window. The prober does not restart during this incident.
After 09:54: HTTPS targets have intermittent failures, followed by sustained failures for most targets around 10:04–10:05 through 10:28. All ten HTTPS probes are successful again by 10:28:30 and remain successful through the window end. Public-IP pings and direct public DNS remain healthy during this later period, apart from the small Cloudflare recovery-window loss noted above. This later application/DNS issue is excluded from the Internet outage duration.

WAN, firewall and local baseline

The pfSense LAN target records 0% one-minute loss throughout. During the requested pre-outage baseline, interval-average WAN download peaks at 0.957 Mbps and upload at 0.368 Mbps. During the core outage (09:42:00–09:53:30 interval endpoints), download is at most 0.00214 Mbps and upload 0.277 Mbps. Per-core CPU load is at most 4% in that core period. No sampled WAN errors or discards increase; ix2 stays operationally up and reports 1000 Mbps link speed. This is Ethernet link status, not proof of DOCSIS connectivity.
The largest download interval in the requested window is 210.576 Mbps ending 09:54:49, with 3.590 Mbps upload: it follows recovery, rather than preceding the outage. Values are approximately one-minute counter-delta averages and cannot exclude very short bursts or congestion elsewhere in the provider network. pfSense SNMP agent uptime increases without resetting; it is not a direct firewall boot-time measurement.

What the new modem data adds

The Hitron CODA5610Q remains in Bridge mode on firmware 7.2.4.5.3b7. Reported LAN and WAN uptime both increase from 63,551 seconds at 09:40:29 to 64,391 seconds at 09:54:29: exactly 840 seconds across 14 minutes, with no observed reset. That is consistent with the operator's report of no power cycle; interface-uptime reset semantics are not independently established, so it cannot rule out every internal modem or DOCSIS recovery action.

The modem API is available through most of the outage, with the single failed poll above. Exporter scrapes remain successful, the login counter stays at one, and WAN packet counters do not reset. Between 09:44:29 and 09:53:29, modem receive packets increase by only 787 (about 1.46 packets/s), while transmit packets increase by 90,034 (about 166.73 packets/s). Modem receive traffic rises sharply again around recovery, consistent with pfSense traffic and public ping observations. These counters' exact coverage in bridge mode remains unverified; transmit counts do not prove successful delivery through the ISP.

The brief modem API failure is correlated evidence of a local management interruption, not proof that the modem caused the Internet outage. DOCSIS power, SNR/MER, channel registration, codeword errors and cable event logs are not available in this dataset.

Collection integrity and comparison with October 18

All saved scrape-health samples are successful. Ping validity stays one, sending continues at one request per second, local ping send/receive error counters remain zero, and the ping process start timestamp is unchanged. There is no evidence here of the previous stuck-ping recovery problem or the Alloy recording-rule ingestion race. Unlike October 18, public-IP pings recover without a prober restart or operator modem power cycle. The 30-second recording-rule offset delays publication; it does not shift the stored measurement timestamps forward.

Conclusion and ISP follow-up

This is strong evidence of an interruption beyond the monitored local gateway path, affecting multiple independent public destinations at low local WAN utilization. It is not evidence of a single website failure or sustained local saturation. The precise failure location remains unproven. Ask the ISP to correlate 13:41–13:54 UTC on October 19 with modem registration/CMTS events, ranging timeouts, RF levels, codeword errors and neighborhood/upstream incidents. Keep the later operator-reported Unbound incident separate from this interval.

Evidence and reproduction

Raw Prometheus API responses: ping.json, services.json, pfsense.json, modem.json and health.json. queries.json records exact selectors and collection time; metadata.json describes scope and alignment. minute-correlation.csv retains source timestamps for aligned values and leaves missing values blank. outage-correlation.png and outage-correlation.pdf share the same saved data. Run build-report.py in this directory with Python, matplotlib and reportlab to regenerate the CSV, chart and PDF offline. No cluster or modem configuration was changed during this review.
